Abstract

Esthetic rehabilitation of a discolored single tooth in the esthetic zone presents major challenges for the clinicians. Due to the advances in dental materials, various conservative and minimal invasive treatment options are available in such cases. The application of the most appropriate treatment option is very important in terms of meeting the aesthetic demands of the patients. Thus, clinical success of a rehabilitation depends on the exact identification of a case and the decision of the appropriate treatment option. This article narrates the esthetic rehabilitaion of a maxillary canine tooth due to fluorosis discoloration with a porcelain laminate veneer restoration.

Keywords: Esthetic Rehabilitation; Maxillary Canine Tooth; Porcelain Laminate Veneer

Introduction

Porcelain laminate veneers are one of the most conservative techniques applied in order to improve or reestablish the dental aesthetics [1-4]. These veneers are better in longevity and the resistance than the other veneer materials [5,6]. Porcelain laminate veneers can be applied in various cases such as discoloration, surface defects, diastema and malformation [1]. The current case report narrates the esthetic rehabilitation of a maxillary canine tooth due to fluorosis discoloration with a porcelain laminate veneer.

Case Report

A 25-year-old female patient reported her discontent with a discoloration at her maxillary left canine tooth (Figure 1). On the clinical examination of the patient, fluorosis related discolorations were observed at the labial medium 2/3 and the inscal part of her left maxillary canine tooth. Radiographic and clinical examination did not reveal any caries or periapical pathological condition. Occlusion was in a class 1 relationship, oral hygiene was good and the gingival tissues were healthy. As a result of the examinations, all appropriate treatment options for this case were described to the patient. Cad/Cam manufactured and individualized by cut-back method porcelain laminate veneer was accepted by the patient as a treatment option.
At the next clinical appointment tooth preparation was performed within minimally invasive approach followed by the final shade selection by utilizing a chromascop shade guide (Vita Toothguide 3D-Master, Vita, Zahnfabrik, Bad Sackingen, Germany). Final impressions were made using a polyvinil-siloxane impression material (Elite-HD, Zhermack, Badia Polesine, Italy) by Putty-Wash technique. Temporary restoration was prepared with a self-curing composite material (Structur Premium, A2, VOCO, Cuxhaven, Germany) and cemented on the tooth surface by applying single point bonding technique (Single Bond, 3M ESPE, St Paul MN, USA).

Porcelain laminate veneer was manufactured by Cad/Cam method (Sirona X5 Scanner - Sirona Inlab 3D Software - Sirona MCX5 Milling Machine, Sirona Dental Systems, Germany; Vitablocs Triluxe Color 1M2, Vita Zahnfabrik, Bad Sackingen, Germany). Individualizations were made in cut-back technique to achieve the proper esthetic result (Vita VM 9 Porcelain, Vita Zahnfabrik, Bad Sackingen, Germany). The coherence and the fit of the laminate veneer were verified both individually and collectively on the prepared tooth. The patient was satisfied with the form, shade and adaptation of the restoration. Final cementation was done with a dual-cure resin cement (Variolink Esthetic Neutral, Ivoclar-Vivadent, Schaan, Lichtenstein) (Figure 2). The occlusion and contact correction with final polishing and finishing process was applied after 24 hours of cementation. Post-operative photos were taken and a night guard oral appliance was performed in order to prevent any trauma on the veneer caused by the parafunctional habits (Figure 3). One year post-operative evaluation did not reveal any fracture or discoloration of the veneer restoration (Figure 4). Patient was pleased with the conformity and esthetics of the restoration.

Discussion

Dental fluorosis is a common disorder affecting the enamel formation at the time of mineralization process. The clinical view exhibits a spectrum of change. Lustless white lines or diffuse opacities are present in its mild form, while in the more severe forms generalized opaque and chalky appearance with confluent pitting and staining of hypo mineralized tissue may be seen [7]. Fluorosis disrupts enamel significantly and affects appearance quite adversely which can cause adverse psychological effects on the individual. The treatment of enamel fluorosis usually ranges from ceramic veneer to direct bonding restorations and bleaching [8]. Although vital bleaching does improve the esthetics to certain extent it has only met with partial success in regard to moderate to severe fluorosis [9].

Porcelain veneers provide precise color match and translucency to the natural tooth and fulfill the need for adequate retention [10]. Veneers is considered to be a more conservative treatment approach compared to full-crown restorations because much less structure is removed from the tooth during the preparation of the veneers. For these types of restorations, the preparation does not cause the reduction of axial walls resulting in preservation of tooth structure and the surrounding hard and soft tissue architecture [11]. Thus, porcelain veneers are an appropriate type of restoration for young adults who have large pulp chambers close to the enamel. Preference of porcelain veneers to re-establish the esthetics in the anterior zone is considered as a satisfactory treatment option. Years of experience with both the technique and the materials utilized offer satisfactory, predictable, and lasting results [12]. Porcelain veneers restore the mechanical behavior and microstructure of the intact tooth in vitro even when they are bonded to an extensive dentin surface using an optimized application mode of dentine adhesives [13].
Conclusion

Veneering a discolored tooth is one of the most appropriate treatment options in the anterior section. Advances in the manufacturing techniques, structural properties of ceramics and luting cements, made porcelain veneering the most acceptable treatment option for the esthetic correction of anterior teeth than the other treatment options. However, clinical process requires high attention to all details in preparation and application process. In addition, adhesion, polishing and occlusion corrections are crucial for clinical success. Current case report presents the esthetic rehabilitation of a discolored maxillary canine tooth with a porcelain laminate veneer.
