Abstract

Currently, animal-to-human transmission of SARS-CoV-2 (COVID-19) has not yet been confirmed, whereas the main mode of transmission is human-to-human. Droplets are the main route of human-to-human transmission, whereas aerosols could be another route in addition to stool-based transmission. Currently, no evidence is available to indicate intrauterine vertical transmission of SARS-CoV-2 (COVID-19) in pregnant women. In the host, the life cycle of coronavirus consists of 5 steps: 1) attachment, 2) penetration, 3) biosynthesis, 4) maturation and 5) release. Once viruses bind to host receptors (attachment), they enter host cells, particularly type II pneumocytes via endocytosis or membrane fusion (penetration). Once viral contents are released inside the host cells, viral RNA enters the host's nucleus for replication and making viral proteins (biosynthesis). New viral particles are produced (maturation) and released. Spike protein of coronaviruses which determines the diversity of coronaviruses and host tropism is composed of a transmembrane trimetric glycoprotein protruding from the viral surface. Structural and functional studies demonstrated that the spike protein of coronaviruses can bind to angiotensin converting enzyme 2 (ACE2), a functional receptor for SARS-CoV. ACE2 expression is high in lung (high expression on lung epithelial cells), heart, ileum, and kidney. The lungs of severe COVID-19 patients demonstrate infiltration of a large number of inflammatory cells. Due to high ACE2 expression on the apical side of lung epithelial cells in the alveolar space, SARS-CoV-2 (COVID-19) can enter and destroy lung epithelial cells. Significant ACE2 expression on innate lymphoid cells (ILC)2, ILC3 and endothelial cells is also demonstrated. Pulmonary endothelial cells represent one third of the lung cells. Endothelial function includes promotion of anti-aggregation, fibrinolysis, and vasodilatation. Due to a significant role playing in thrombotic regulation, hypercoagulable profiles that are demonstrated in severe COVID-19 patients likely suggest significant endothelial injury. Pulmonary thrombosis and embolism accompanying elevation of d-dimer and fibrinogen levels have been demonstrated in severe COVID-19. In conclusion, further studies on understanding the roles of ILC1, ILC2, ILC3, including the difference in response to SARS-CoV-2 (COVID-19) infection between children and adults are urgently needed to develop efficient targeted therapies.

Introduction

Available data observed from China and India revealed that the individuals with age group of 20 - 50 year are likely to be infected by the SARS-CoV-2 (COVID-19) [1,2]. Singapore and Germany took measures by ramping up COVID-19 testing capacity quite early and by ensuring that all persons had equal opportunity to get tested, thus ensuring positive COVID-19 results early during COVID-19 progression. This meant that most cases were mild symptoms [3]. South Korea constantly informed their people about the development of COVID-19 by using the a centralized messaging system and media. South Korea also used the Trace, Test, and Treat protocol to rapidly identify and isolate COVID-19 patients, while the United States limited this to severe COVID-19 patients with later broadening of this criterion as well as India and many European countries. South Korea also ensures free COVID-19 diagnostic testing through the universal healthcare, unlike the United States.

Currently, animal-to-human transmission of SARS-CoV-2 (COVID-19) has not yet been confirmed, whereas the main mode of transmission is human-to-human. Droplets are the main route of human-to-human transmission, whereas aerosols could be another route [4] in addition to stool-based transmission [5,6]. Currently, no evidence is available to indicate intrauterine vertical transmission of SARS-CoV-2 (COVID-19) in pregnant women [7]. The Indian government concerns on how to identify and contain asymptomatic SARS-CoV-2 (COVID-19) carriers, who could account for approximately 80% of COVID-19-infected individuals [8]. As all of SARS-CoV-2 (COVID-19) may not develop the disease, asymptomatic SARS-CoV-2 (COVID-19)-infected carriers are at major risk of being superinfect with COVID-19 [9]. Some investigators hypothesize that a warm climate could reduce transmission by preventing SARS-CoV-2 (COVID-19) from surviving for longer periods of time on surfaces.

Mechanism of SARS-CoV-2 (COVID-19) invasion into host cells

Coronaviruses are enveloped and single-stranded ribonucleic acid (RNA) viruses of approximately 30 kb with infections of various host species [10]. SARS-CoV-2 (COVID-19) are divided into four genera; α, β, γ and δ based on their genomic structure. Alpha and beta coronaviruses infect only mammals [11]. SARS-CoV-2 (COVID-19), SARS-CoV and Middle-East-Respiratory-Syndrome coronavirus (MERS-CoV) are classified to β coronaviruses.

In the host, the life cycle of coronavirus consists of 5 steps: 1) attachment, 2) penetration, 3) biosynthesis, 4) maturation and 5) release. Once viruses bind to host receptors (attachment), they enter host cells, particularly type II pneumocytes via endocytosis or membrane fusion (penetration). Once viral contents are released inside the host cells, viral RNA enters the host’s nucleus for replication and making viral proteins (biosynthesis). New viral particles are produced (maturation) and released.

Coronaviruses consist of four structural proteins; spike (S), membrane (M), envelop (E), and nucleocapsid (N) [12]. Spike protein of coronaviruses which determines the diversity of coronaviruses and host tropism is composed of a transmembrane trimetric glycoprotein protruding from the viral surface. Spike protein comprises two functional subunits; S1 subunit is responsible for binding to the host cell receptor and S2 subunit is responsible for the fusion of the viral and cellular membranes. Structural and functional studies demonstrated that the spike protein of coronaviruses can bind to angiotensin converting enzyme 2 (ACE2) [13-15], a functional receptor for SARS-CoV [16]. ACE2 expression is high in lung (high expression on lung epithelial cells), heart, ileum, and kidney [17]. Further studies are needed for additional SARS-CoV-2 (COVID-19) binding targets.

After binding of SARS-CoV-2 (COVID-19) to the host protein, protease cleavage is underwent by the spike protein. Activation of the spike protein of SARS-CoV-2 (COVID-19) and MERS-CoV as a two-step sequential protein cleavage has been proposed as a model that consists of cleavage at the S1/S2 cleavage site for priming and a cleavage for activation at a position adjacent to a fusion peptide within the S2 subunit “S2” site [18-20]. Following the cleavage at the S1/S2 cleavage site, S1 and S2 subunits remain non-covalently bound and the distal S1 subunit leads to the stabilization of the membrane-anchored S2 subunit at the pre-fusion state [14]. Presumably activation of the spike protein for membrane fusion through irreversible and conformational changes is due to subsequent cleavage at the S2 site [21]. Existence of furin cleavage site (“RPSPA” sequence) at the S1/S2 site is the unique characteristics of SARS-CoV-2 (COVID-19) among coronaviruses. During biosynthesis, the S1/S2 site of SARS-CoV-2 (COVID-19) is entirely subjected to cleavage in a drastic contrast to SARS-CoV spike protein that is incorporated without cleavage [14]. The expression of furin makes SARS-CoV-2 (COVID-19) very pathogenic although the S1/S2 site is also subjected to cleavage by other protease, such as cathepsin L and transmembrane protease serine 2 (TMPRSS2) [20,22].

T-cell mediated responses against coronaviruses are antigen presentation through dendritic cells (DCs) and macrophage that can phagocytize virus-infected-apoptotic epithelial cells contributing to antigen presentation to T cells. The expression of ACE2 on (splenic) dendritic cells and pulmonary alveolar macrophages is present but limited, based on the Immunological Genome database (http://rstats.immgen.org). DCs and macrophages may be primarily infected with virus. SARS-CoV-2 (COVID-19) uses another protein to bind to antigen presenting cells (APCs) or not should be investigated. These APCs move to the draining lymph nodes to present viral antigens to T cells. In addition to ACE2, SARS-CoV can also bind to dendritic-cell specific intercellular adhesion molecule-3-grabbing nonintegrin (DC-SIGN, high expression on dendritic cells and macrophages) and DC-SIGN-related protein (DC-SIGNR, L-SIGN) [23-25]. CD8+ T cells kill viral infected cells, whereas CD4+ T cells activate B cells to promote the virus-specific antibody production.

Patients with severe COVID-19 demonstrated lymphopenia, especially in peripheral blood T cells [26,27] and increased plasma concentrations of granulocyte-colony stimulating factor (G-CSF), interleukin (IL)-6, IL-10, macrophage inflammatory protein (MIP)-1α, monocyte chemoattractant protein 1 (MCP-1), and tumor necrosis factor (TNF)-α [26-28]. The higher levels of IL-6 are the more severe conditions the COVID-19 patients are in. Higher expression of CD38, CD44, and CD69 is demonstrated in COVID-19 patients with activation of CD4+ and CD8+ T cells. T cells exhaustion that could have led to the progression of COVID-19 is indicated by higher percentage of checkpoint receptor Tim-3+ FB-1+ subsets in CD4+ and CD8+ T cells. Another marker for T cells exhaustion is elevation of NK group 2 member A (NKG2A) on CD8+ T cells [29]. Aberrant pathogenic CD4+ T cells with co-expressing interferon (IFN)-γ and granulocyte-macrophage colony-stimulating factor (GM-CSF) are demonstrated in severe COVID-19 patients [26]. Significant decrease in circulating T cells, the majority of infiltrating adaptive immune cells are primary cytotoxic CD8+ T cells. CD4+ T cells are also pathological cytotoxic T cells found in severe COVID-19 patients [30] with lung injury [31]. These pathological CD4+ T cells release circulating monocytes responding to GM-CSF. Significant higher percentage of CD14+CD16+ inflammatory subsets are also identified in COVID-19 patients, but they are seldom exist in health individuals. These inflammatory CD14+CD16+ inflammatory monocytes demonstrate high IL-6 expression, that accelerates the progression of systemic inflammatory response. GM-CSF, a response to virus infection can assist in differentiation of innate immune cells augment T cell function, but GM-CSF can trigger tissue damage at excess [32,33]. Previous experimental autoimmune encephalomyelitis (EAE) models in adults revealed that GM-CSF+IFN-γ+CD4+ T cells were demonstrated upon strong T cell receptor (TCR) responses, whereas CD8+ T cells expressing GM-CSF were identified at higher percentage and secreted IL-6. Neutrophils, the majority of innate immune cells can induce lung injury [34-36].

In addition to IL-6 production, SARS-CoV-infected lung epithelial cells produce IL-8, a well-known chemoattractant for neutrophils and T cells [37]. The three main components for innate immunity in human airway are epithelial cells, pulmonary alveolar macrophages, and dendritic cells (DCs), whereas DCs are located underneath the epithelium and macrophages reside at the apical side of the epithelium [37]. The lungs of severe COVID-19 patients demonstrate infiltration of a large number of inflammatory cells [38,39]. Due to high ACE2
expression on the apical side of lung epithelial cells in the alveolar space [40, 41], SARS-CoV-2 (COVID-19) can enter and destroy lung epithelial cells. Significant ACE2 expression on innate lymphoid cells (ILC)2, ILC3 [42], and endothelial cells [43,44] is also demonstrated. NK cells, a member of ILC1 constitute a majority of pulmonary ILCs, approximately 95 %, whereas ILC2 and ILC3 are responsible for mucous homeostasis. Nevertheless, there is a very limited knowledge of ILC2- and ILC3-involved coronavirus infection. Pulmonary endothelial cells represent one third of the lung cells [45]. Endothelial function includes promotion of anti-aggregation, fibrinolysis, and vasodilatation [46]. Due to a significant role playing in thrombotic regulation [46], hypercoagulable profiles that are demonstrated in severe COVID-19 patients likely suggest significant endothelial injury. Pulmonary endothelial injury can facilitate viral invasion through abnormal microvascular permeability. Pulmonary thrombosis and embolism accompanying elevation of d-dimer and fibrinogen levels have been demonstrated in severe COVID-19. The clinical features of SARS-CoV-2-infected patients vary from minimal symptoms to severe respiratory failure with multiple organ failure, in addition to pulmonary thrombosis and embolism. Computed tomography (CT) of the chest in COVID-19 patients reveals the characteristic pulmonary ground glass opacification even in the asymptomatic patients [47].

The difference of pathophysiology between children and adults in COVID-19 is hypothesized as the following: 1) The expression level of ACE2 may differ between children and adults [41], 2) Children have a qualitatively different response to the SARS-CoV-2 (COVID-19) virus to adults [48] and 3) The simultaneous presence of other viruses in the mucosa of lungs and airways that are common in young children can contribute to SARS-CoV-2 (COVID-19) virus compete with them and limit its growth [49].

Conclusion

Some questions involving SARS-CoV-2 (COVID-19) are needed to be answered include: 1) Do asymptomatic persons develop the disease at any point in time at all?, 2) How long do the patients shed the virus for?, 3) Do the patients eventually develop antibodies? and 4) Is SARS-CoV-2 (COVID-19) stored in any individuals' tissue in a dormant state? Additionally, further studies on understanding the roles of ILC1, ILC2, ILC3, including the difference in response to SARS-CoV-2 (COVID-19) infection between children and adults are urgently needed to develop efficient targeted therapies.

Authors Contributions

Dr. Attapon Cheepsattayakorn conducted the study framework and wrote the manuscript. Associate Professor Dr. Ruangrong Cheepsattayakorn contributed to scientific content and assistance in manuscript writing. Both authors read and approved the final version of the manuscript.

Competing Interests

The authors declare that they have no actual or potential competing financial interests.

Funding Sources

The authors disclose no funding sources.
